conservation measures. Restricted-use demand forecasts were made for Lancaster, Palmdale, and the Antelope Valley on the basis that the same "best-management practices" for water-demand reduction were used for Antelope Valley as were used in Perris Valley, a similar desert area in California (Metropolitan Water District of Southern California, 1993). These model runs were produced only for reference because no "best-management practices" have been adopted for the study area.

Attempts to forecast water demands for the Antelope Valley area were made using information available for the cities of Lancaster and Palmdale (tables 10 and 11) for which water demand was

forecasted through the year 2010 (table 12). Preliminary calibration and verification indicate that sufficient socioeconomic data presently (1994) are not available for the Antelope Valley to use the current forecasts from the MAIN system without extreme caution. Data are limited for employment (table 13), median income distributions (table 14), and housing statistics for single family (table 15) and multifamily (table 16) housing units. Population data are available (table 17), but often are contradictory for the same year from different sources. Of the three forecasts made using the MAIN model, the Lancaster simulation contained the highest quality socioeconomic data available. The forecasts presented in table 12 indicate that the

¹See table 13.

²Must have base year information for this option.

reported water demands for 1990 account for about 70 to 77 percent of the simulated water demands forecasted under unrestricted and restricted scenarios. However, none of the water suppliers in the study area have adopted "best-management practices" for water conservation that were used in simulating our restricted water-demand projections. The differences between our present simulated and reported water demands for 1990 are expected to decrease as input data for the model systems are improved and as accuracy increases in accounting for actual water demands for Lancaster, Palmdale, and the entire Antelope Valley.

Assuming that growth in water demand and projected socioeconomic variables for Lancaster are representative of the Antelope Valley, total urban water demand in the Antelope Valley is projected (using the MAIN system) to increase from about 77,168 acre-ft (actual) in 1990 (table 12 and table 18 at back of report) to about 329,000 acre-ft in 2010 (table 12). More conservative projections can be derived using the ratios of increase in urban demand forecasted (table 12) between 1990 and 2010 for Lancaster or Palmdale. The ratio of increase for Lancaster is 2.08, determined from a reported water demand of 32,430 acre-ft in 1990 and a forecasted water demand of 67,490 acre-ft in 2010. The ratio of increase for Palmdale is 2.50, determined from a reported water demand of 23,950 acre-ft in 1990

and a forecasted water demand of 59,940 acre-ft in 2010. Using reported total water demand of 77,168 acre-ft/yr for all urban uses for the entire Antelope Valley in 1990 and these ratios, projected urban water demands for Lancaster and Palmdale would increase between 1990 and 2010 from 23,736 acre-ft to 49,371 acre-ft for Lancaster, from 17,192 acre-ft to 42,980 acre-ft for Palmdale, and from 77,168 acre-ft to between 160,500 and 192,920 acre-ft for the Antelope Valley. A more liberal projection for total demand for all urban uses can be derived by applying the ratio of increase between 1990 and 2010 for the entire Antelope Valley (109,910 in 1990 to about 329,000, or 2.99). Using this projection, urban water demand would increase from 77,168 acre-ft in 1990 to 230,732 acre-ft/yr by 2010.

This wide range of projected water demand (160,500 to 329,000 acre-ft) is indicative of the expected error associated with the present water-demand forecasts made using socioeconomic data currently available for the Antelope Valley. Management of local water resources is expected to be decided by members of the Antelope Valley Water Group (and other interested parties) on the basis of these projections, their best judgement, and their understanding of local conditions. In addition to potentially significant errors in population projections and other model parameters, other factors can

PWS-0197-0057

Table 12. Water-demand forecast for the Antelope Valley and the cities of Lancaster and Palmdale, 1980 to 2010

[Method used: These forecasts were developed using a version of the MWD_MAIN water-demand forecasting system supplied by the Metropolitan Water District of Southern California (1993) for the Perris Valley area. The Perris Valley system was modified to reflect conditions as they presently (1994) are known for the Antelope Valley. The assumption for the best-management practices are the same as were used for Perris Valley, California, by the Metropolitan Water District of southern California to create restricted-use estimates. This assumption was made because no best-management practices have been adopted in the Antelope Valley. USGS, U.S. Geological Survey; gal/d, gallons per day; acre-ft/yr, acre feet per year; --, no data available]

System run	Forecast year	Annual water-demand forecast				Reported water demand use (from table 18 and USGS data base)

¹Percent of forecasted demand that is accounted for in our data base (table 18). The difference between reported and forecasted could be due to incomplete reporting and/or unrefined forecast data for the Antelope Valley forecasts. Another potential source of error for the Lancaster and Palmdale forecasts occurs when determining the actual deliveries to each city by each water supplier when city and water boundaries are different.

²Housing values, water rates, and winter rainfall for Lancaster and the Antelope Valley.

affect future water demands, including construction of the proposed international airport and high-speed rail systems. Water-conservation options may be adopted along with other current best-management practices to help better manage future water demands in the Antelope Valley. Because estimated increases in water demand are relative to increases in population, most of the increase in water demand in the Antelope Valley is expected to be for urban uses. Population projections for 2010 show that the population, which was probably between 250,510 and 273,443 in 1990 according to available reports, could increase to 738,000 in 2010 and 986,000 by 2020, which represent increases of 295 and 394 percent, respectively (table 17).

Disaggregated Factor Forecasts

An alternative approach to MAIN system forecasts, which may be more appropriate in areas of limited data availability such as the Antelope Valley, is the Disaggregated Factor Forecast (DFF) method. The DFF is a simplified version of the MAIN system which can provide a sectoralized result. This method reportedly could be used on a simple spreadsheet or with a hand-held calculator. Advantages of this method include simplicity, ease in use, and fewer data requirements; the primary disadvantage is a loss in accuracy. Because of the anticipated loss in accuracy, this method has not yet been applied in the Antelope Valley. However,

now that interim forecasts have been made with the MAIN systems, it may be valuable during the next iteration of forecasting to see how close the estimate might be if this method is used.

Forecasts for Military Installations

The interim water-demand forecasts made in this report for the Antelope Valley using the MWD-MAIN system have included Edwards Air Force Base in the public-supplied category. This inclusion is justified because Edwards Air Force Base is a licensed public water supplier. However, water-demand forecasts for military installations are not adequate when using the MAIN system because MAIN requires Standard Industrial Classifications, which are not available for military base activities.

The need for water-supply planning at military installations resulted in the development of a specialized system called IWRAPS (Installation Water Resources and Planning System) that can produce water-demand forecasts for military installations during peacetime and mobilization scenarios. IWRAPS is based on parameters that are available for military bases, such as square footage of installations, weather, and irrigated acreage. This system was developed by Planning and Management Consultants, Ltd., under contract to the U.S. Army Corps of Engineers. IWRAPS is based on information that identifies areas of specific water use at a military installation by specific function, which is based on the mission of the installation. A new version of IWRAPS, developed specifically for air force bases, was successfully applied at Vandenberg Air Force Base in Santa Barbara.

Table 14. Median income distribution for the Antelope Valley

[--, no data available]

Sources of data:

Income: Javier Minjares, Southern California Association of Governments (written commun., 1993) for Lancaster and Palmdale incomes in 1980, 1984, 1987, and 1990; Alfred Gobar and Associates (1993) for Antelope Valley incomes in 1980 and 1990. Eva Opitz, Planning and Management Consultants, Ltd. (written commun., 1993) for 2000 and 2010. Consumer Price Index, for the Los Angeles/Long Beach area, Frank Nion, Southern California Association of Governments (written commun., 1993). All reported income figures were adjusted to 1980 dollar values using the Consumer Price Index for the Los Angeles/Long Beach area (Javier Minjaries, Southern California Association of Governments, written commun., 1993). Income forecasts were projected using a 6-percent increase per 10-year period, which is consistent with income forecasts for Los Angeles County used in the MAIN systems from Metropolitan Water District of Southern California (Eva Opitz, Planning and Management Consultants, Ltd., oral commun., 1993). Income distributions for 1980, U.S. Department of Commerce (1980) for Lancaster and Palmdale and Alfred Gobar and Associates (1993) for the Antelope Valley.

County, California. This system has a great deal of potential for application at Edwards Air Force Base in the Antelope Valley. When this system is

implemented for Edwards Air Force Base, IWRAPS is expected to improve and enhance the overall water-demand forecast for the Antelope Valley.

DATA-BASE DEVELOPMENT AND ANNUAL UPDATE PROCEDURE

The data base for this study was compiled using ARC/INFO, a geographic information system, and Quattro Pro, a spreadsheet software. Site-specific and aggregated water-supply, land-use, socioeconomic, and demographic data make up the data base.

Data from various water agencies were obtained in computer-readable format or were entered

manually if computer-readable versions were not available or were incompatible with software used for this study. Computerized data were available from Antelope Valley-East Kern Water Agency, California State Water Resources Control Board, Metropolitan Water District of Southern California, Palmdale Water District, and the Southern California Association of Governments.

An annual update procedure could include contacting each water supplier, as well as the State Water Resources Control Board, for the most recent

data for a calendar year. Annual updates to this data base would be greatly facilitated if each of the agencies supplying water in the valley used a common format for data storage or stored the same basic information in their data systems. A more formal agreement could be established with each water supplier and major water user to supply their annual updates as they become available. An annual review of the list of water suppliers and users would be needed to improve confidence in the adequacy of the data, and users might need to be added or removed each year.

WATER-RESOURCES MANAGEMENT CONSIDERATIONS

Demand on available water supplies for the Antelope Valley were reported to be 127,361 acre-ft in 1991 and, on the basis of recent forecasts, are projected to be between 127,000 and about 329,000 (tables 2 and 12) acre-ft by 2010. In 1991, reported water demands in the valley totaled about 127,361 acre-ft: 91,743 acre-ft came from ground-water supplies; 27,396 acre-ft came from imported surface-water supplies; 1,669 acre-ft came from local surface-water supplies; and 6,553 acre-ft came from reclaimed wastewater supplies (table 2). Imported water from the State Water Project normally would have been a larger percentage of the total supply, but the availability of that water was severely affected by the 1987-92 drought. Additional ground water was used to meet the demand.

The ground-water system in the Antelope Valley is a naturally stable, long-term, but finite source of water. Average ground-water recharge is estimated to be about 40,000 to 58,000 acre-ft/yr (Snyder, 1955; Bloyd, 1967; Durbin, 1978). When ground-water use exceeds replenishment, water levels decline and the source becomes depleted. Ground water in the Antelope Valley was depleted extensively during the peak agricultural period of the 1950's. Ground-water depletion in recent years can be estimated on the basis of ground-water pumpage data presented in figure 10 (assuming the true value for 1988 is the average of 1987 and 1989). Assuming that recharge averaged 40,000 to 58,000 acre-ft/yr, the average rate of ground-water depletion from 1983 to 1991 would have been about 8,000 to 26,000 acre-ft/yr. Recharge may have been less than the annual long-term average during that period because of below average precipitation (fig. 2) and related surface runoff

during the drought. Ground-water depletion during 1983-91, therefore, could have been greater than that estimated above.

Adverse consequences of ground-water-level declines include increased pumping lifts, reduced well efficiency, and the potential for aquifer-system compaction and associated land subsidence that can result in damage to public infrastructures. The economic effects of increased pumping lifts and reduced well efficiency include increased power requirements to pump the same volume of water and the eventual need for deeper wells as water levels approach the bottom of existing screened intervals. Economic and environmental effects of aquifer-system compaction and associated land subsidence in the Antelope Valley include fissures, sinkholes, broken well casings, decreased hydraulic head in the aquifer system, and unstable vertical datum, which is used for constructing drainage and flood-control structures. Additional potential effects caused by subsidence include insurance and legal implications, flood-control problems, and damage to structures, transportation facilities, and agricultural land. Maximum measured land subsidence was 6.0 ft from 1926-92, with about 4.7 ft occurring after 1957 (Ikehara and Phillips, 1994, table 8).

Management of water supply and water demand (including conservation of available water resources) is becoming an increasingly popular option available to water-resource managers. Recent efforts throughout the arid west have indicated that great water savings are possible when best-management practices are used. Currently (1994), no water suppliers in the Antelope Valley have adopted local best-management water-conservation practices.

Blomquist (1992) writes "Groundwater basin management represents a deliberate effort to derive greater benefits from the use of this resource while avoiding its depletion and the associated human welfare costs." A deliberate management effort is needed to meet future water demands in the Antelope Valley without incurring the economic and environmental costs associated with overuse of the ground-water resource. Part of this effort could involve the conjunctive use of surface and ground water. When available, excess local or imported surface water can be stored underground for use during periods of peak demand, such as in 1991 when imported water supplies were severely reduced. The managed, conjunctive use of surface and ground water can serve to meet demands during

periods of drought and to mitigate land subsidence and other potential adverse effects of ground-water storage depletion.

Some water suppliers in the Antelope Valley have adopted a conjunctive-use practice called the "in lieu of pumping" program as documented by the California Department of Water Resources (1980). This program involves the use of imported surface water in addition to (or instead of) ground-water pumpage. The net result is less ground water pumped within the valley. Ground-water pumpage still could continue to increase but at a lower rate than if ground water were the sole water source (fig. 8).

Efficient capture, storage, and management of local surface water, imported surface water, and reclaimed wastewater would be an integral part of a conjunctive-use program in the Antelope Valley. With the exception of reclaimed wastewater, the volume of water available from these sources is highly variable—minimal during periods of drought and abundant during storms or years of above average precipitation. The ability to capture or obtain and store water from these sources when it is available is limited by economic and physical factors. These factors include the costs and feasibility of building and maintaining facilities to capture, store, and treat these water resources.

SUMMARY AND CONCLUSIONS

Land use and water use in the Antelope Valley, California, have varied significantly since development of the valley began in the late 1800's. Ground water has been a major source of water supply in this area because of limited local surface-water resources. Completion of the California Aqueduct to this area in the early 1970's imported water from the Sacramento-San Joaquin Delta, about 400 mi to the north. Estimates of ground-water pumpage, which previously have been published, increased from about 29,000 acre-ft in 1919 to about 400,000 acre-ft in the 1950's. Declines in ground-water levels and increased costs for electrical power in the 1970's decreased the quantity of ground water pumped annually for irrigation uses. Total annual reported ground-water pumpage decreased to about 53,200 acre-ft in 1983 and increased to about 91,700 acre-ft in 1991 as a result of the 1987-92 drought. Rapid urban

development, coincidental with several years of drought, renewed concerns about a possible return to extensive ground-water-storage depletion and increased land subsidence. In 1992-93, a water-use survey was done in the Antelope Valley to identify current and historical quantities of water use.

Forecasts in this report indicate that increased water demands will continue with continued urban development. These forecasts are based on projections of population growth and other socioeconomic variables provided by various agencies. Although the availability of socioeconomic data is limited and many sources of error are inherent in the forecasting process, preliminary results indicate that water demands could increase from 127,361 acre-ft in 1991 to between 127,000 and about 329,000 acre-ft by 2010. Various forecasting options are identified. The reliability of forecasting results for the Antelope Valley is controlled by the availability of input data needed for the forecasting method selected and data on actual water demands. The level of detailed information needed to make decisions on local water-resources management is expected to be made by members of the Antelope Valley Water Group and other interested parties. Potential water-resource management actions for the Antelope Valley include (1) increasing artificial ground-water recharge when excess local runoff (or imported water supplies) are available, (2) implementing water-conservation best-management practices, and (3) optimizing ground-water pumpage and conjunctive-use throughout the basin.
